## Acknowledgements

Several individuals provided valuable support for this project. The Intellectual Capital Partnership Program inspired the development of new ways to value higher education. We thank Joy Hymel, Executive Director; Terry Durden, Director of Operations; and Will Hearn, Program Director, for encouraging us to pay more attention to the employment needs of certain economic sectors and explore effective ways of using USG graduates' wage information.

The Board of Regents planning group challenged us to depict future scenarios for longrange planning. We thank Shelley Clark Nickel, Special Assistant to the Chancellor, and Dr. Cathie Mays Hudson, Associate Vice Chancellor, for involving us in the planning process, which served as the inspiration for the external migration analysis in Section 4 of this report.

Assistant Commissioner Amelia Butts and her staff at the Georgia Department of Labor's Workforce Information and Analysis Unit furnished vital information for this analysis. In particular, recent occupational employment demand projections for 2010 were critical to our analysis.

This report reflects the conclusions of the authors, and not of the Georgia Institute of Technology or the sponsor.

## **Executive Summary**

What is the value of higher education? The University System of Georgia's (USG) Intellectual Capital Partnership Program (ICAPP) has asked Georgia Tech to examine this question in studies conducted over the past six years. Through these studies, a rich base of knowledge has been developed in three areas:

- Demand and shortfall analysis, which addresses the question, Are there enough USG graduates in high-demand occupations?
- Migration analysis, which addresses the question, What impacts do USG institutions have on the flow of students across the state?
- Wage analysis, which addresses the questions, To what extent does higher education yield greater earnings, and, What is the impact on state and county economies?

### **Demand and Shortfall Analysis**

New 2010 projections from the Georgia Department of Labor indicated that <u>higher</u> <u>education-related occupations will compose 25 percent of all jobs in 2010</u>, an increase over 2000 levels. Georgia's top three higher education-related occupations based on numeric employment increases are forecast to be registered nurses, computer support specialists, and accountants and auditors; and based on percentage increases, survey researchers, computer support specialists, and physician's assistants.

These projections were compared to the number of graduates from all postsecondary institutions in the state in 2000 by major area of specialization. <u>USG was the single largest</u> <u>supplier of higher education graduates, producing nearly half of all of Georgia's graduates.</u> The shortfall analysis also accounted for the number of workers moving into the state (minus the number leaving) based on new data from the 2000 census.

<u>Only 12 higher education-related occupations were found to have shortfalls of more</u> <u>than 100</u>. The largest shortfall was in elementary and kindergarten teaching occupations. Four health care occupations also had significant shortfalls: registered nurses, pharmacists, medical records and health information technicians, and medical and clinical laboratory technicians. <u>Shortfalls in the information technology area were significantly reduced</u>, although scarcities continued in certain computer software engineering and systems occupations. The shortfalls in these 12 occupations exceed 3,000 unfilled positions annually.

#### **Migration Analysis**

The top 12 occupations with shortfalls of more than 100 a year would have had nearly double the deficits without in-migration. Forecasts through 2025 suggest that Georgia will have fewer in-migrants than in the past. Because in-migrants tend to have higher education levels than those staying in the state, the decline in in-migration may have a detrimental affect on the state's ability to fill higher education-related occupations.

Workers migrate within the state as well as between states. Based on a gravity model, researchers found that the location of USG institutions significantly affects the internal flow of graduates in the state. Graduates are more likely to work in the local area after graduation, especially graduates of research universities. Also, the size of the pool of graduates has a significant effect on intrastate migration.

#### Wage Analysis

An economic impact analysis of the value of higher education in Georgia drew on a methodology developed by the U.S. Census Bureau in its 2002 landmark study "The Big Payoff." A comparison of the earnings of high school graduates to USG graduates showed that **graduating from a USG institution paid off**. Not only did it pay off to the average graduate in the 1993 to 1997 timeframe, to the tune of about \$14,000 in 1998, but more significantly, it paid off to the state as a whole, by nearly \$1.25 billion. And it paid off to 93 counties, which benefited by more than \$1 million from USG graduate earnings. These impacts reflect only a single year of

benefits in the careers of a five-year graduate cohort. The total benefits could be as much as 40 times higher over this cohort's full work-life.

#### **Future Directions**

Based on these findings, USG should continue to monitor the relationship between supply and demand at the state and sub-state levels, given projected changes in in-migration. USG should also initiate another round of matching of its graduates with Georgia Department of Labor employment security data for multiple years beyond 1998. It is further recommended that the wage-based economic impact analysis be extended to a more complete benefit-cost analysis to better demonstrate the value of higher education in Georgia.

Section 1 Introduction

#### Introduction

For the past six years, the Board of Regents of the University System of Georgia (USG) through the Intellectual Capital Partnership Program (ICAPP) has asked Georgia Tech to examine the relationship between the demand for workers in various occupations and the supply of postsecondary institutional program graduates. The most recent study (referred to here as the 2001 study) showed that three factors were important in understanding the economic development impact of higher educational institutions from a human capital perspective— migration, shortfall, and wages. It reported that while most university-related occupations were well supplied by workers from the USG, other postsecondary institutions, and people moving into the state, there was a significant shortfall of information technology (IT) workers. (Drummond and Youtie, 2001)

In the intervening period, the information technology sector shrank along with the rest of the economy. Public-sector cutbacks have become necessary to balance many state and local budgets. In this climate, policy-makers pay increased attention to value of state services, including highly regarded services such as higher education. Traditionally, the value of higher education has been portrayed based on institutional and student spending. Such methodologies compute capital expenditures on buildings and equipment, salary and operating expenses, and purchases made by students and apply multipliers to estimate the extent to which these expenditures generated subsequent rounds of additional spending. (Humphries, et al., 1999; Duhart, 2002.) This is a very useful methodology that has been applied to a broad range of public programs—from education to prisons to road construction.

Although spending by higher educational institutions is important, the core mission of universities and colleges is to educate students. Students undertake higher education for many reasons, but the chief one is that they expect it to lead to future economic success. It would be particularly beneficial to identify methodologies that can capture the economic value of this education mission on the future economic success of students.

#### Scope of Work

This study aims to demonstrate the value of higher education from three perspectives. First, it will examine the benefits of higher education in addressing the employment needs of high-demand occupations. Section 2 will present recently released employment projections for 2000 to 2010 and show the fastest-growing occupations requiring higher education in Georgia and the nation. Section 3 will relate these projections to the existing supply of USG graduates and graduates of other postsecondary institutions in the state, as well as the supply of in-migrants based on information from the 2000 U.S. Census released in June 2003. This analysis will highlight which higher education-related occupations are unlikely to have enough graduates and in-migrants to fill employers' needs through 2010.

Second, Section 4 of this study will investigate the relationship between USG institutions and migration. Migration has two components: external migration and internal migration. The former looks at the extent to which the state can continue to expect educated workers from other state to fill high-demand occupations in Georgia. Projections from the U.S. Census Bureau through 2025 by educational attainment will be the primary source of data for the external migration analysis. Internal migration focuses on the impact of USG institution location on the flow of students into the economy. Specifically, it examines the extent to which USG institutions affect where a student chooses to work (relative to other factors such as level of wages offered and home county influences).

An economic impact analysis of the value of higher education is presented in Section 5. In its recent landmark study, "The Big Payoff," the U.S. Census Bureau developed an approach for using wages and educational attainment to demonstrate the economic value of education. (Day and Newburger, 2002). Annual earnings of higher education graduates were compared to annual earnings of high school graduates, and the difference was deemed to be the value of higher education. "The Big Payoff" estimated that college graduates earn 1.8 times more than high school graduates. Section 5 presents a variation of the methodology in "The Big Payoff" to show the overall impact of USG institutions and programs on state and county economies.

# Section 2 Future Demand for College Education

What is the demand for employees with college education? One way to answer this question is by investigating occupations that require higher education. The U.S. Bureau of Labor Statistics has found in national surveys that certain occupations are linked to certain levels of education and work experience. (Wash, 1996). For example, physicians and lawyers typically have a professional degree; school teachers typically have a bachelor's degree; medical technicians typically have an associate's degree; general managers typically have work experience plus a bachelor's degree; cashiers typically have short-term on-the-job training; and upholsterers typically have long-term on-the-job training. By knowing the demand for employees in these occupations, one can address the demand for higher education.

#### **How Occupational Demand Is Forecast**

Occupational employment demand is based on long-range projections that use sophisticated econometric models. These models account for the size and demographic composition of the labor force, the growth of the aggregate economy, final demand or gross domestic product (GDP), and interindustry relationships (input-output). Surveys of employers conducted every three years by the Georgia Department of Labor furnish information for the instate estimation process. Projections are first made for industries, then a staffing pattern matrix is used to produce projections by occupation.

This set of projections marks the first time that standard occupational classifications (SOCs) were used. Projections were made for nearly 650 SOCs nationally and more than 750 occupations in Georgia. Unfortunately, no sub-state occupational employment projections were available for SOCs 2010, so researchers did not conduct a regional supply-demand analysis

### Georgia's Fastest-Growing Higher Education-Related Occupations Are Similar to the Nation's

Which occupations are projected to add the most jobs? There are two approaches to determining the fastest-growing jobs: numerical growth and percentage growth. Numerical growth shows the raw numbers of job openings over the next 10 years. Table 2.2 compares numerical growth projections for Georgia and the nation, focusing only on occupations that generally require a university degree. The top two occupations with the most projected new jobs

are the same in Georgia as in the nation—registered nurses and computer support specialists. Accountants and auditors are on both lists, but rank higher in Georgia than in the nation.

A second way to examine the fastest-growing occupations is percentage growth. Percentage growth indicates how fast employment changes will occur. Table 2.3 compares the percentage growth in jobs projected for higher education-related occupations in Georgia and the nation. Survey researchers are the occupation with the biggest percentage growth rate in Georgia whereas computer software applications engineers top the national list. Computer support specialists rank second on both lists, but physician's assistants rank third on the Georgia list compared to eighth on the national list.

### **College Education Will Be More Important to Georgia in 2010**

Georgia will add 805,570 new jobs through 2010 or nearly 20 percent more new jobs than in 2000. Occupations that typically require higher education will account for a larger share of jobs in 2010 than in 2000. By 2010, a higher education degree will be required for occupations employing nearly 25 percent of workers compared to 23 percent in 2000. Occupations linked to all types of college degrees—from associate's to doctoral and professional degrees—will compose a greater share of the workforce in 2010 than in 2000, whereas those requiring on-the-job training or work experience will represent a declining share of new jobs in 2010. (See Figure 2.1 and Table 2.4.)

## Figure 2.1. College Degrees Will Account for a Larger Share of the Jobs in 2010 than in 2000\*

\*This chart represents the percentage of jobs in 2010 requiring certain degrees or non-college training minus the percentage of jobs in these same categories in 2000. Source: Georgia Department of Labor, 2003.

### Conclusions

Georgia's 2010 workforce will present new challenges. There will be more than 800,000 new jobs than in 2010. While three-quarters of these jobs still require no formal college degree, the latest projections show that these jobs are on a declining path. College degree-related jobs will account for 1.5 percent more of the jobs in 2010 than in 2000. This may not seem like much, but it represents more than 262,000 new jobs. More important, it shows that college education will be even more valuable to Georgia's citizens and ultimately to the Georgia economy than it is today.

## Table 2.4. Every Category of College Degree-Related Occupations Is Increasing in Percentage of Total Jobs in 2010, While Non-Degree Occupations Are Decreasing

					Percent
	2000			2010 Percent	•

Section 3 Shortfall Analysis Shortfall analysis estimates the long-term need that Georgia companies will have for employees in particular occupations. This estimate is over and above employment needs filled by postsecondary institution graduates available for hire and employees moving into the state (minus the number leaving the state). All estimates are based on 10-year projections made in 2000.

Four elements compose shortfall analysis. These are summarized in Table 3.1 and described in the sections that follow.

#### **Annual Job Openings**

#### Annual Openings

For this analysis, researchers used annual openings, rather than the 10-year growth rates discussed in Section 2. Annual openings enable comparisons to be made with other annual data such as the supply of university graduates in a given year. Annual openings are based on annualized 10-year growth rates; however, they also include net replacements. Net replacements consist of workers who transfer from other

#### Table 3.1. Shortfall Analysis – University System

**Annual job openings** in occupations typically requiring a university degree, projected from 2000-2010

MINUS **Supply of graduates in majors** for 1999-2000 in all public and private postsecondary institutions in Georgia

MINUS **Supply of net migrants** or employees (in occupations typically requiring a university degree) coming into Georgia from other states (and out from Georgia to other states) from the 2000 census

EQUALS Occupations with **annual shortfalls** through 2010

occupations or who leave the workforce, but do not include persons leaving the state, and persons changing occupations.

#### **Occupational Supply**

This study defines occupational supply as the number of graduates by major from all Georgia's postsecondary educational institutions. The significance of the supply component in the shortfall analysis is as follows. If postsecondary institutions continue to graduate the same number of students with the same majors, what impact will that have on filling the demand for workers in occupations critical to the state's economy?

To estimate supply, researchers gathered data on number of graduates by major in

Georgia's postsecondary institutions. These institutions include USG colleges and universities, private colleges and universities, Georgia Department of Technical and Adult Education (DTAE) colleges, and nonprofit and proprietary technical institutions. The Integrated Postsecondary Education Data System (IPEDS) serves as the primary data source for occupational supply analysis. Administered by the National Center for Educational Statistics (NCES) of the U.S. Department of Education, IPEDS includes national, state, and institution-level information (such as enrollment program completion, faculty, staff, finances, and academic libraries) from some 12,000 postsecondary institutions. The most recent data available on completions (graduates) from these institutions is as of 2000. More recent data about graduates is directly available from the USG and DTAE. However to maintain comparability with private institutions, researchers relied on the 2000 IPEDS data.

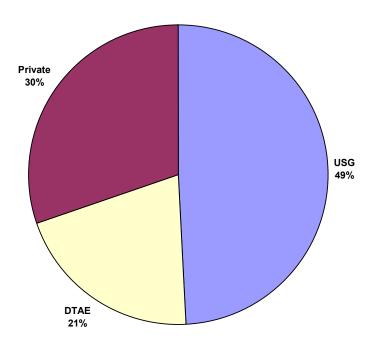

The USG is the major source of postsecondary graduates in the state. About half of all postsecondary institution graduates in Georgia were educated by a USG institution. (See Figure 3.1.) The USG also supplies roughly 60 percent of all graduates with associate's degrees. USG is even more important for bachelor's level and higher education. Two-thirds of all graduates with bachelor's, master's, doctoratal, and professional degrees came from a USG institution.

#### Figure 3.1. Nearly Half of All Higher Education Graduates Are from the University System of Georgia

	N	Percent of Graduates

## Table 3.2. Number of Degree Graduates by Level and Type of Georgia Institution,Academic Year 2000.

Source: Georgia Tech's City Planning Program and Economic Development Institute, calculated from U.S. Department of Education IPEDS 2000 data.

The occupational supply analysis focuses on the data relating to the classification of instructional programs (CIP). The CIP represents all primary fields of study leading to degrees or certificates. There are nearly 900 such classifications.

#### Net Migration

As part of the shortfall forecasts, Georgia Tech researchers estimated the effects of net migration of talent into the state. Net migration, or the number of people moving into the state minus the number leaving the state, is an important factor in Georgia. During the April 1, 2000 to July 1, 2001 time period, Georgia ranked third among all 50 states in domestic net migration and eighth in international net migration.

The 2001 study showed that there are two types of migration. The first type consists of graduates of Georgia institutions who leave the state immediately after graduation. International or out-of-state students may go back to their home regions. Some students may remain in the state but leave the Georgia workforce for personal reasons. As a result, the first year sees a rather big loss. To estimate the size of this out-migration, researchers used an earlier data set that combines USG student data with Georgia Department of Labor workforce data. Seventy percent of the graduates from 1993-1997 were found in the 1998 workforce data. From this comparison, researchers calculated graduate loss rates by institution.

The second type of migration is slower and steadier. Smaller numbers of people drift in or out of the state over time or leave the Georgia workforce for personal reasons. The best source of state-to-state occupational migration data has been the U.S. Decennial Census and its resulting Public Use Microdata Sample (PUMS) data sets. These data sets were just released in the second quarter of 2003. To track Georgia's out-migrants, researchers analyzed data for each of the 50 states (plus Washington, D.C.) to find out who previously lived in Georgia. To track Georgia in-migrants, researchers simply processed the Georgia data. Based on this data, a net migration rate was calculated for each SOC in Georgia and applied to the employees in that SOC, resulting in the number of net migrants for each occupation.

The state has gained more workers than it has lost in nearly all occupational categories. The top five higher education-related occupations based on net migration are registered nurses, accountants and auditors, business operations specialists, elementary school teachers, and computer support specialists. More than 800 employees in these five occupations combined are estimated to move to Georgia each year.

#### Crosswalk and Shortfalls

To link the major occupational and instructional classification information, a crosswalk translation database from the National Crosswalk Service Center (NCSC) was used. NCSC employs survey-based relationships to determine the links between graduates and their majors and occupations.

Georgia Tech researchers used the crosswalk to allocate graduates, net migrants, and occupational employees. Researchers applied the crosswalk across the entire spectrum of occupations, not just the university-educated subset. Thus, not all the graduates in the university CIPs map into the university occupations.

With graduates, net migrants, and occupational employees linked, a simple subtraction furnishes projected shortfalls.

#### **Findings**

#### **Only 12 Higher Education-Related Occupations Have Sizable Annual Shortfalls**

Table 3.3 shows that there are 12 higher education-related occupations with annual shortfalls of more than 100. The vast majority of occupations do not have significant shortfalls because their needs are filled either by USG or other postsecondary graduates or by in-migration. Most companies' needs for new employees will likely be met through 2010. Nevertheless, the shortfalls in these 12 occupations come to more than 3,000 unfilled positions annually.

Elementary school teachers represent the largest shortfall. Nearly 1,000 elementary school teacher jobs a year are projected to go unfilled. Even with more than 800 teachers coming into the state and nearly 800 graduating from postsecondary institutions, the shortage of elementary school teachers is projected to continue through 2010.

Four higher education health care occupations have significant shortfalls. Three are at the associate's degree level—registered nurses, medical records and health information technicians,

and medical and clinical laboratory technicians. There is also a shortage of pharmacists, who typically must have bachelor's degrees.

The biggest change from the 2001 study is that shortfalls in IT-related occupations are much smaller. The only IT-related occupations with a shortfall of more than 100 are computer software engineers for applications and systems software and computer systems analysts. This shortfall is still significant, but not as large as previously determined.

#### **Education Occupations**

Elementary school teachers were the only educational occupation with significant shortfalls. Because Georgia does not offer separate educational programs for kindergarten and elementary school, this analysis has grouped them together. The shortfall finding should be viewed as a joint kindergarten-elementary teacher annual shortfall.

#### Health Care Occupations

Shortfalls in health care occupations are a national, if not global, problem. Such is the case in Georgia. About 32 percent of health care jobs with university degree connections are projected to go unfilled. This represents an annual shortfall of more than 2,000 a year. (See Table 3.4.) Most significant is the shortfall of registered nurses, followed by pharmacists. There are also shortfalls in various physician specialties—particularly family and general practitioners, surgeons, dentists, and internists. Physician shortfalls may not cause serious problems because other states produce significant oversupplies that spill over into Georgia. Nevertheless, monitoring of the supply and demand of physicians should be continued to maintain the quality of health care in the state.

Table 3.3. Occupations With Statewide Shortfalls of More than 100 Annually
Through 2010

**Bioscience Occupations** 

Georgia Tech researchers conducted a companion study of supply and demand in bioscience occupations. (Drummond and Youtie, 2003) State and national occupational employment forecasts call for long-term shortfalls in medical and clinical laboratory technician and technologist positions. However, current demand measures do not show a great shortage of medical and clinical laboratory technicians and technologists, and executive interviews even suggest that there are plenty of technicians for the number of available bioscience positions in Georgia today. Not all medical and clinical laboratory technicians will work in a bioscience company; most will work in health care services settings. Still, Georgia institutions do not offer programs that produce significant numbers of graduates for these positions. As a result, many of these technician-level positions in Georgia are probably being filled by workers receiving onthe-job training or moving from related occupations. Educators should track the relationship between demand for medical and clinical laboratory technicians and the supply of graduates through 2010 to assess when shortfalls dictate the need for increasing technician training resource allocation.

Also significant were concerns about the lack of experience of the state's bioscience graduates. Nine of 10 bioscience openings require industry-relevant experience. This is particularly true of research and management positions, which can require up to five or more years of experience. And although executives interviewed for this study mentioned having needs to fill positions in a diverse range of occupations (e.g., biostatistician, regulatory affairs, quality assurance), the common thread was the need for professionals with specialized experience in these positions. It was recommended that relevant corporate or government experience be incorporated into the existing curriculum in partnership with local industry, and that certificate programs be considered for executives.

#### Information Technology Occupations

Shortfalls in the information technology occupations have been significantly reduced since the 2001 study. There are still some shortfalls in certain information technology occupations, especially computer software engineers. Nevertheless, taking all information technology occupations together, the demand for these workers is nearly balanced with the supply. Almost half of all the information technology-related jobs come from in-migration of

out-of-state specialists, so it is important for the state to continue to monitor the relationship between supply and demand for these workers given their important role in economic development.

#### Limitations

These shortfall results should be interpreted in the context of limitations of the analysis. Demand projections are long-term forecasts, which cannot reflect short-term fluctuations in certain sectors (e.g., layoffs in the high-tech sector) or business changes that may make an occupation seem less attractive (e.g., managed care practices, which may have discouraged workers from taking health care positions). At the same time, these long-term forecasts can be influenced by the economic, demographic, technological, and policy circumstances that exist during the base year, which for this analysis was 2000.

The relationship between supply and demand is constrained by the way that postsecondary educational institutions categorize their major programs. For example, shortfalls may appear in a given occupation when in fact Georgia institutions are graduating students that could take jobs in this occupation, but their major area is coded in a category not typically linked to the occupation. Finally, students have the freedom to pursue certain jobs or majors because of reasons unrelated to the education-occupation link—wanting to live in a certain city, desire jobs with certain working conditions (e.g., those that offer telecommuting, casual clothes). For these reasons, common sense and industry review must be used in interpreting the shortfall findings.

# Section 4 External and Internal Migration

#### The Importance of Migration

Migration of educated workers to Georgia is vital to the state's economy. The top 12 occupations with shortfalls of more than 100 a year would have had nearly double the shortfalls without in-migration. In many cases, the number of net migrants is a larger source of workers than are the graduates of all Georgia's higher educational institutions combined.

This section will examine two types of migration: (1) external migration from other states into Georgia, and (2) internal migration within Georgia.

#### **External Migration**

#### Approach

Will Georgia be able to continue its reliance on educated workers from other state's to fill jobs in critical occupations? The external migration analysis addresses this question by examining migration projections published by the U.S. Census Bureau through 2025. The Census Bureau has two population projection series. Series A bases its forecasts on historic migration. This series has traditionally been the most accurate predictor of state-to-state migration. Series B uses employment projections from the U.S. Bureau of Labor Statistics to drive its migration projections. Both series use the same method to account for births and deaths in the natural population. They differ only in the way they account for migration.

#### **Findings**

#### Georgia May Not Be Able to Rely on Migration to Fill Employment Needs

Even though Georgia is projected to retain its position among the top 10 states with the most in-migration, the state can expect fewer in-migrants in the future. (See Table 4.1.) According to Series A projections, Georgia's 2025 net migration will only be 30 percent of 2000 net migration levels. Series B projections indicate that the state's 2025 net migration will be only 76 percent of 2000 net migration levels. (See Figure 4.1.) In either case, Georgia will have fewer annual net migrants than it has in the past.

1995 Series A&B			2025 Series A (Historic Migration)				2025 Series B (Emp. Migration)			
Rank	State	Рор	Rank	State	Рор	Rank	State	Рор		
1 2 3 4 5 6 7 8 9	California Texas New York Florida Pennsylvania Illinois Ohio Michigan New Jersey	31.6 18.7 18.1 14.2 12.1 11.8 11.2 9.5 7.9	2 3 4 5 6 7 8	California Texas Florida New York Illinois Pennsylvania Ohio Michigan <b>Georgia</b>	49.3 27.2 20.7 19.8 13.4 12.7 11.7 10.1 <b>9.9</b>	2 3 4 5 6 7 <b>8</b>	California Texas Florida New York Illinois Pennsylvania Ohio <b>Georgia</b> Michigan	41.5 28.2 20.1 19.4 13.7 12.9 12.3 <b>11.0</b> 10.4

Population in millions and projections are for July 1. Series A and B reflect different interstate migration assumptions.

Source: U.S. Bureau of the Census, Population Division, PPL-47, table 1.

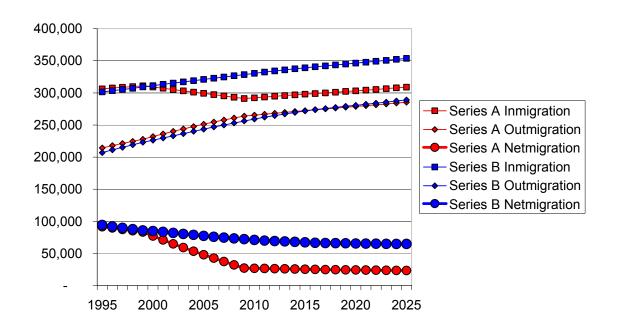

Figure 4.1. In-migration and Out-migration From 1995 to 2025: Series A and Series B Projections

#### In-migrants and Out-migrants – More Educated Than Continuous Residents

This potential migration problem is even more serious because in-migrants and outmigrants have higher education levels than do continuous residents of Georgia. Table 4.2 and Figure 4.2 present data from the 2000 census showing education levels for adults over 25 who enter Georgia, leave Georgia, and stay in the state. Fifteen percent of continuous residents have bachelor's degree or higher. But 25 percent of in-migrants and 29 percent of out-migrants hold bachelor's degrees.

Both series show out-migration will increase, meaning that Georgia may lose a greater number of workers with higher education. Series A shows in-migration decreasing, so Georgia will have fewer of these highly educated in-migrants. Series B shows in-migration increasing, but not as rapidly as out-migration does. In either case, the net migration decline will have a particularly detrimental effect on the state's ability to fill higher education-related occupations.

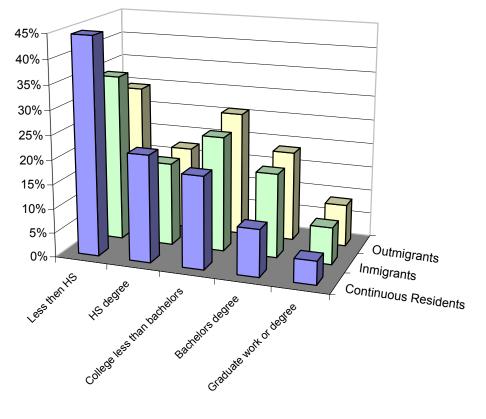

## Table 4.2. Levels of Education of Georgia Residents, In-migrants, and Out-migrants

Level of Education	Continuous Residents	In-migrants	Out-migrants	Continuous Residents In-	migrants Out	-migrants
Less then High School High School degree	3,110,905 1,535,412	413,406 206,422	188,767 111,156	45% 22%	34% 17%	29% 17%

#### **Internal Migration**

In addition to migration between states, the USG and its institutions are affected by intrastate migration. Intrastate migration raises questions such as:

- Are students more likely to go to school in a location near their home county?
- Are students more likely to work in a location near their home counties?
- Are students more likely to work in a location near their educational institution?
- How local is the draw area for different types of USG institutions?
- By adding a new institution to a new location, or by changing the type of an existing institution, how would the systemwide distribution of students change?
- By adding a new institution to a new location, how many more graduates would be likely to stay to work in the area?

#### Method

One of the best ways to address internal migration is by following graduates of USG institutions into their first jobs. By matching the USG's student database to the Georgia Department of Labor's (DOL) employment database, it is possible to track each individual student from home county, to institution, to work county. The first matching effort involved linking USG graduates during the 1993-1997 academic years to the DOL 1998 employment database, which provides a rich foundation to build models of intra-state migration.

The basic statistical-geographical model utilized for this analysis is the gravity model. A gravity model is much like Newton's discovery that gravitation attraction between two bodies is a function of the size of the bodies and distance between them.<sup>2</sup>

C \* empa \* pop $\beta / d\gamma$ 

<sup>&</sup>lt;sup>1</sup>For the last two years, this research team has worked with the Board of Regents staff to procure an updated version of this dataset that would include employment information for 1998 to 2002. The updated dataset could not be secured in time for inclusion in this study. Thus, the models presented in this section are based upon the original 1998 dataset. Although these models make sense and show much promise, before any policy decisions can be based on them it will be necessary to develop a more robust, multi-year dataset.

 $<sup>^{2}</sup>$  In a typical social science application of the gravity model, the number of employees working in one location and living in a second location is equal to

where C is a constant, emp is the number of employees in the first location, pop is the population at the second location, and d is the distance between the locations. The parameters  $\alpha$ ,  $\beta$ , and  $\gamma$  can be understood as weights, with

To understand the student migration model, assume a high school student lived in Columbus, attended college at Statesboro, then after graduation worked in Savannah. Figure 4.3 shows the "flow" path of that student. The magnitude of this flow will be larger when the number of students in the home county is larger, the size of the institution is larger, and the size of the workforce in the work county is larger. The flow will decrease the longer the home county-school county distance, and the longer the school countywork county distance.

Figure 4.3. Student Flow Path: Home, School, Work

There is a third factor. We would expect that the distance between the student's home

county and work county would also be important. Because of familiarity and contacts generated through family and friends, a student might be more likely to work in a county near to his or her home county. (See Figure 4.4.)

Wages are an important fourth factor. Locations with higher wages are likely to offer an additional attraction to graduates seeking work in certain locations across the state. The model also accounts for instances where home and work counties are identical or adjacent.<sup>3</sup>

Figure 4.4. Flow Path of Student Working Near Home County

larger parameter values giving more weight to that factor, and smaller (nearer to 0) weights giving less weight. <sup>3</sup> The model can be written as

If low =  $lC + \alpha$ \*lhgrads +  $\beta$ \*lsgrads +  $\gamma$ \*lwgrads +  $\delta$ \*lhstime +  $\epsilon$ \*lhwtime +  $\zeta$ \*lswtime The six parameters (and constant) of this equation can then be estimated by multiple regression.

There are seven other control variables added to the equation, including lewage: natural log of the expected wage in the work county

hwsame: 1 if the home county and work county are the same, 0 otherwise

hwadj2: 1 if the home county and work county are adjacent, 0 otherwise

Flow = C \* hgrads<sup> $\alpha$ </sup> \* sgrads<sup> $\beta$ </sup> \* wgrads<sup> $\gamma$ </sup> \* hstime<sup> $\delta$ </sup> \* hwtime<sup> $\varepsilon$ </sup> \* swtime<sup> $\zeta$ </sup> Instead of dividing by the distances, researchers rewrite the model in multiplicative terms, and expect that the final three parameters will be negative.

For each home county-school county-work county flow, researchers know the hgrads (the number of USG students from a county), the sgrads (the number of students at the school), the wgrads (the number of workers found in the work county), the hstime (home-school travel time in hours), the hwtime (home-work travel time in hours), and the swtime (school-work travel time in hours). By taking the natural log of both sides of the flow equation above, the equation is transformed into

#### Findings

Detailed regression results for this model can be found in Appendix 1. Figure 4.5 shows the model parameters (for the systemwide model) superimposed over the Columbus-Statesboro-Savannah example. The red parameters show that the size of the institution and the size of a county's workforce are equal, with less importance for the number of students coming from the home county. The blue numbers show the distance effects. If any of these were zero, it would mean that distance has no effect on the flow of graduates. The home-work distance is the most important distance factor (-

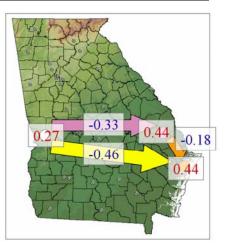

Figure 4.5. Model Results: Home, School, Work Flow Path Weights

.46), with the home-school the next most important (-.33), and the school-work the least important of the three (-.18). Yet it should be noted that the location of the school does have some influence on USG graduates' work location decisions. The school-work factor is statistically significant and not zero. The county from which a student comes still has more influence on where a student works, however.

Overall, we found that the location of a USG institution significantly affects the locational behavior of USG graduates.

- A 10 percent increase in the size of the home county student population (whose parameter is 0.27) produces a 2.7 percent increase in the flow of students from that county to that institution.
- A 10 percent increase in institution size produces a 4.4 percent increase in the flow of students to that institution.
- A 10 percent increase in a county's college graduate workforce generates a 4.4 percent increase in the flow of students to that county.
- A 10 percent increase in the distance between home and school decreases the flow of students by 3.3 percent.

 A 10 percent increase in the distance between school and work decreases the flow of students by 1.8 percent.

The model also found that a 10 percent increase in wages in a county means that 10.5 percent more graduates would flow to that area. There is an extra likelihood that students will attend an institution in their home (or adjacent) county, return to their home (or adjacent to home) county to work, or work in the same county where they attended college.

In addition to the overall model, researchers conducted special analyses of four types of USG institutions: research institutions, other four-year institutions, two-year institutions, and historically black institutions. First, the model indicates that graduates of the research institutions are less sensitive to changes in wages than graduates of the other types of institutions. For research institution graduates, a 10 percent increase in wages produces only a 2.5 percent increase in graduates taking positions. Second, more two-year students come from the school's county and adjacent counties relative to other types of institutions. Third, graduates of historically black institutions have a greater tendency than other types of institutions to stay in the local area after graduation.

Finally, an examination of the distance parameters yields several interesting findings. The home-school distance is especially important for the historically black institutions (parameter of -0.81). These students are very sensitive to distance and tend not to travel far from their home counties to attend school. It is not surprising that students at research universities are least sensitive (-0.24) to home-school distance. The home-work distance factor is reversed: it has little effect on students at historically black institutions (-0.01), and the most effect (-0.55) on students at research institutions. The latter may be due to the tendency of research universities to be located in large urban areas, where many students come from and where many jobs exist

#### Conclusions

Georgia may not be able to rely on an ever-increasing stream of educated in-migrants to fill important occupational categories in the future. USG should track net migration, especially by education and occupation, to assess if and when decreasing in-migration into the state impacts critical university-related occupations.

At the same time, attention must also be paid to intrastate migration. A gravity model found that the location of USG institutions has a significant effect on the internal flow of graduates in the state. The distance between home and school is important, particularly to graduates of two-year and historically black institutions. Graduates are more likely to work in the local area after graduation, especially graduates of research universities. Also the size of the pool of graduates has a significant effect on intrastate migration. The USG should pay attention to the effect of its institutions on the distribution of graduates and potential workers in various regions across the state.

# Section 5 Economic Value of USG Students: A Wage-Based Analysis

There are many ways to portray the economic impact of higher education. While educational institutions generate significant value from expenditures and capital projects, higher education's most compelling impact on the state's economy may be its influence on the earnings of its students.

This analysis will answer the question: "In economic terms, what is the value of our graduates to the state of Georgia?" There are many personal and social benefits to higher education, but this analysis will be restricted to estimating the economic benefits of USG graduates to the state of Georgia.

#### Method

The most accurate way to determine the economic worth of higher education would be to estimate what a person's earnings would have been without higher education. Ideally the analysis would include statistical controls for personal characteristics such as intelligence, energy, and creativity, then estimate the increment of earnings due to additional education, holding the control variables constant. Yet such variables are difficult to measure and extraordinarily expensive to obtain.

Instead, this report presents a modification of the U.S. Census Bureau's study "The Big Payoff" (Day and Newburger, 2002). It assumes that the economic value of higher education can be estimated by comparing the earnings of high school graduates to the earnings of those completing, two-year, four-year, and graduate degrees. The (presumably) positive increment of earnings is assumed to be the value of higher education.

The basic data source for this analysis is the matched database of 1993-97 USG graduates and 1998 Georgia Department of Labor worker records referenced in the previous section. To estimate wages for full-time workers more accurately, the analysis is restricted to those earning \$10,000 or more in 1998, producing a dataset of 83,329 individual graduates.

There is one significant difficulty with this approach. The matched graduate-worker dataset only contains information on those completing degrees; there is no information on persons graduating from high school and not completing a USG degree. Fortunately, we can overcome this difficulty by using the recently released PUMS dataset from the U.S. Census

Bureau. The PUMS data contains a 1 percent sample of the Georgia population, and includes a weight factor that allows data aggregations to reflect the population as a whole. Because it is microdata (individual records without any identifying information), researchers can create any type of cross-tabulation and are not restricted to the tables published by the Census Bureau.

Table 5.1 was produced from the PUMS dataset (excluding those earning more than \$10,000 per year), and shows the relationship between education and earnings for those aged 21-30 (the approximate age range of those included in the graduate-worker matched dataset). Table 5.2 contains similar estimates for the graduate-worker dataset. In Table 5.2, an estimated earnings value of \$22,000 for high school graduates produces similar ratios of higher education values, and matches exactly the earnings ratio for bachelor's degrees to high school graduates.

Level of Education	1999 Earnings	0
No schooling completed	\$ 19,960	
Nursery school to 4th grade	22,941	
5th grade or 6th grade	18,161	
7th grade or 8th grade	19,280	
9th grade	21,977	
10th grade	21,445	
11th grade	21,522	
12th grade, no diploma	20,758	
High school graduate	24,012	0%
Some college, but less than 1 year	25,354	5%
One or more years of college, no degree	25,619	6%
Associate's degree	28,593	16%
Bachelor's degree	36,429	34%
Master's degree	39,772	40%
Professional degree	48,869	51%
Doctoral degree	44,412	46%

High School Graduate (estimated)	\$22,000	0%
Certificate	29,585	26%
Bachelor's	33,261	34%
Master's	43,567	50%
Professional	54,796	60%
Doctoral	53,883	59%

Table 5.2 Earnings Due to Higher Education by Education Level

Source: USG-Georgia Department of Labor matched dataset, 1998.

The wage analysis estimates incremental earnings due to higher education by applying the percentages in the second table to the earnings reported in the graduate-worker matched dataset. These estimates calculate the economic value of recent graduates (1993-1997) for the 1998 Georgia economy. In general, the incremental percentage of earnings due to higher education increases as educational levels increase. Higher education accounts for only 16 percent of the earnings of an associate's degree graduate, but up to 60 percent of the earnings of a graduate with a professional degree such as law or medicine.

### Findings: Total Economic Impact of USG in 1998 – Nearly \$1.25 Billion

The USG's total economic impact on the Georgia economy in 1998 was nearly \$1.25 billion. The average value of a USG education to its roughly 90,000 graduates was just under \$14,000 per graduate. Table 5.3 presents the economic impact of higher education on recent graduates of USG institutions. Based on total impact, the top two institutions are Georgia State University and University of Georgia, each representing a total economic impact from higher education of more than \$200 million apiece, followed by the Georgia Institute of Technology with a total economic impact of more than \$100 million. On a per graduate basis, Medical College of Georgia, Georgia Institute of Technology, and Georgia State University had the highest economic impacts of more than \$18,000 per graduate.

Institutional rankings depend on the types of instructional programs offered. Appendix 2

presents the 1998 economic impact of higher education on recent graduates for the top 10 most lucrative instructional programs based on total and average values. The top program in terms of total impact is business administration, followed by nursing and teaching. This ranking reflects the large numbers of students who graduate with these majors. The three top programs with the greatest average values are the professional degrees—dentistry, medicine, and law.

Institution	Count	Total Wages	Educational Value	Average Wage	Ed	Average ucational Value

Figure 5.1 maps the total economic impact in millions of dollars, and Figure 5.2 maps the average impact per USG graduate. In 93 counties across the state, the USG had a per-county economic impact of more than \$1 million in 1998. USG's impact was more than \$10 million in 17 counties, mostly in Atlanta and Georgia's mid-sized cities. (See Appendix 3 for a listing of impacts by county.)

It is important to remember that this impact is only for one year's worth of benefits (1998) to a single graduate cohort (1993 to 1997 graduates). A more complete cost-benefit analysis would extend these benefits over a full 40-year career. Benefits thus could be as large as 40 times the total impact indicated in this report.

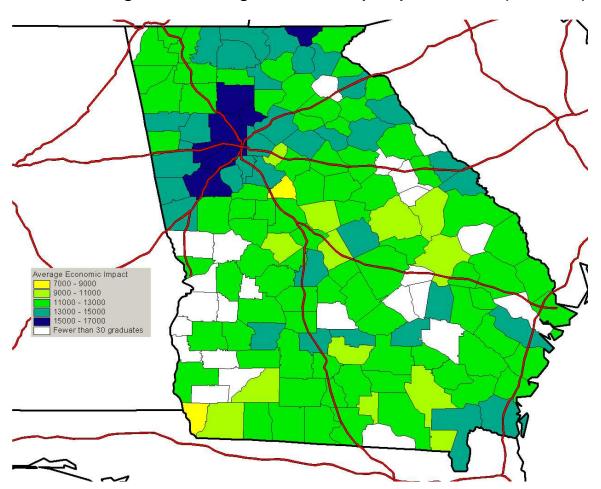

Figure 5.2: Average Economic Impact per Graduate (in Dollars)

### Conclusion

Drawing on the methodology developed by the U.S. Census Bureau in its study, "The Big Payoff," this analysis has shown that graduating from a USG institution pays off. Not only did it pay off to the average graduate in the 1993 to 1997 time period, to the tune of about \$14,000 in 1998, but more significantly it paid off to the state as a whole, by nearly \$1.25 billion. It also paid off to 93 counties, each of which benefited by more than \$1 million from USG graduates. These impacts reflect only a single year (1998) in the careers of a five-year (1993-1997) graduate cohort. The total benefits could be as much as 40 times higher over this cohort's full work-life.

Section 6 Future Directions This report has examined the value of a USG education from three perspectives: (1) filling jobs in high demand occupations, (2) impacting the migration of graduates within the state, and (3) demonstrating the economic impact of USG education on the state's 1998 economy. The demand-based shortfall analysis continues USG's tradition of monitoring needs for talent in high-demand occupations requiring university education. It shows that the state faces significant health care shortfalls, along with shortages of elementary school teaching and selected IT positions, a situation which calls for a central role for the USG. The migration study introduced new techniques for examining critical issues. The migration analysis presented projections of declining in-migration of educated workers from other states into Georgia through 2025. This finding suggests that close attention should be paid to the needs of high-demand occupations and the extent to which the state must step up to fill employment gaps caused by reduced numbers of in-migrants. This report also introduced new techniques for showing the vital role that USG plays in the state's economy based on educational attainment and wages.

These analyses should be continued in several future directions. First, the regional shortfall analysis should be updated as new projections become available from the Georgia Department of Labor. Sub-state regional projections are due to be updated in the coming year.

Second, the USG should initiate another round of matching of its graduates with Georgia Department of Labor employment security data for multiple years beyond 1998. This larger database would enable an updated tracking of USG graduates and facilitate a more complete understanding of the impact of particular USG institutions on intrastate migration.

Third, the wage-based economic analysis presented in this report should be extended to a full wage benefit-cost analysis. This benefit-cost analysis should incorporate resident instruction expenditures and be applied to all graduates (not just the most recent ones). Such an analysis would show the extent to which the full benefits of higher education compare to the costs of providing this education. In tight economic times, such information can be particularly worthwhile in demonstrating the value of higher education.

## Appendix 1 Intrastate Migration Model

The following table shows the models estimated for all students at all institutions, then four additional models that separately estimate parameters for four-year institutions, historically black institutions, research institutions, and two-year institutions. The dependent variable is the home county-school county-work county flow of students (with all flows below 5 omitted), weighted by the size of the flow.

	Variable	All USG Institutions	Four Year Inst.	Hist. Black Inst.	Research Inst.	Two Year Inst.

\*\*\* Parameter is significant at the .001 level of significance.

Г

LFLOW	natural log of the flow of students from home county to	(number of students flowing over
	school county to work county	this home-school-work path)
LHGRADS	natural log of the number of USG graduates from the home county	(size of sending population from home county)
LSGRADS	natural log of the number of students at the institution	(size of institution)
LWGRADS	natural log of the number of USG graduates found working in the county	(size of employment in work county)
LEWAGE	natural log of USG graduate wages in the working county	(wages)
LHWTIME	natural log of home county-work county travel time	(home-work distance)
LHSTIME	natural log of home county-school county travel time	(home-school distance)
LSWTIME	natural log of school county-work county travel time	(school-work distance)
HWSAME	home county and work county are the same	(home-work local effect)
HWADJ2	home county and work county are adjacent	(home-work regional effect)
HSSAME	home county and school county are the same	(home-school local effect)
HSADJ2	home county and school county are adjacent	(home-school regional effect)
SWSAME	school county and work county are the same	(school-work local effect)
SWADJ2	school county and work county are adjacent	(school-work regional effect)

Due to the multiplicative nature of the gravity model, the regression parameters involving natural logarithms can be interpreted as elasticities. An elasticity of 1.0 means that a 10 percent increase in the value of an independent variable produces a 10 percent increase (or decrease, if the parameter sign is negative) in the value of the dependent variable.
